

## Vector Algebra

### Definition

A vector  $\mathbf{A}$  has a magnitude  $A = |\mathbf{A}|$  and a direction given by the unit vector  $\hat{\mathbf{a}} = \mathbf{A} / |\mathbf{A}|$ .

In Cartesian coordinates  $(x, y, z)$ , we find

$$\begin{aligned}\mathbf{A} &= \hat{\mathbf{a}} A = \hat{\mathbf{x}} A_x + \hat{\mathbf{y}} A_y + \hat{\mathbf{z}} A_z \\ &= (A_x, A_y, A_z)\end{aligned}$$

(a) Base vectors

(b) Components of  $\mathbf{A}$

Ulaby Figure 3-2

6.1

NOTE: This vector notation using boldface type goes back to Josiah Willard Gibbs, a 19-th century American physicist. It is sometimes therefore referred to as GIBBS NOTATION. Maxwell just wrote out all the equations longhand.

## Vector Algebra

### Definition

We also have

$$A = (A_x^2 + A_y^2 + A_z^2)^{1/2}$$

$$\hat{\mathbf{a}} = \frac{\hat{\mathbf{x}}A_x + \hat{\mathbf{y}}A_y + \hat{\mathbf{z}}A_z}{(A_x^2 + A_y^2 + A_z^2)^{1/2}}$$

UMBC

(b) Components of  $\mathbf{A}$

Ulaby Figure 3-2

## Vector Algebra

### Equality

Two vectors **A** and **B** are equal if

$$A_x = B_x, A_y = B_y, \text{ and } A_z = B_z$$

### Addition and Subtraction

$$\mathbf{C} = \mathbf{A} + \mathbf{B} = \mathbf{B} + \mathbf{A} \quad (\text{addition is commutative})$$

$$= \hat{\mathbf{x}}(A_x + B_x) + \hat{\mathbf{y}}(A_y + B_y) + \hat{\mathbf{z}}(A_z + B_z)$$

$$\mathbf{D} = \mathbf{A} - \mathbf{B} = \mathbf{A} + (-\mathbf{B})$$

$$= \hat{\mathbf{x}}(A_x - B_x) + \hat{\mathbf{y}}(A_y - B_y) + \hat{\mathbf{z}}(A_z - B_z)$$

**UMBC**  
AN HONORS  
UNIVERSITY  
IN MARYLAND

(a) Parallelogram rule

(b) Head-to-tail rule

Ulaby Figure 3-3

6.3

Ulaby et al. makes a distinction between *equal* and *identical* vectors. Identical vectors start at the same point.

## Vector Algebra

### Position and Distance vectors

For a point  $P(x, y, z)$ , the *position vector*  $\mathbf{R}$  goes from the origin to the point

$$\mathbf{R} = \hat{\mathbf{x}}x + \hat{\mathbf{y}}y + \hat{\mathbf{z}}z$$

The distance vector between two points

$P_1(x_1, y_1, z_1)$  and  $P_2(x_2, y_2, z_2)$  is defined as

$$\begin{aligned}\mathbf{R}_{12} &= \mathbf{R}_2 - \mathbf{R}_1 \\ &= \hat{\mathbf{x}}(x_2 - x_1) + \hat{\mathbf{y}}(y_2 - y_1) + \hat{\mathbf{z}}(z_2 - z_1)\end{aligned}$$

where  $\mathbf{R}_i = \hat{\mathbf{x}}x_i + \hat{\mathbf{y}}y_i + \hat{\mathbf{z}}z_i$ ,  $i = 1, 2$

The distance  $d$  between two points

equals  $|\mathbf{R}_{12}|$

$$d = |\mathbf{R}_{12}|$$

$$= \left[ (x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2 \right]^{1/2}$$

Ulaby Figure 3-4

Note that the point 1 corresponds to the tail and the point 2 corresponds to the head of the vector. That way  $\mathbf{R}_2 = \mathbf{R}_1 + \mathbf{R}_{12}$ .

## Vector Algebra

### Multiplication — Simple Product

When a vector  $\mathbf{A}$  is multiplied by a scalar  $k$ , the magnitude is multiplied by  $k$  and the direction is unchanged

$$\begin{aligned}\mathbf{B} &= k\mathbf{A} = \hat{\mathbf{a}}(kA) \\ &= \hat{\mathbf{x}}(kA_x) + \hat{\mathbf{y}}(kA_y) + \hat{\mathbf{z}}(kA_z)\end{aligned}$$

### Multiplication — Scalar or Dot Product

The scalar or dot product of two vectors  $\mathbf{A}$  and  $\mathbf{B}$  is defined by

$$\mathbf{A} \cdot \mathbf{B} = AB \cos \theta_{AB}$$

where  $\theta_{AB}$  is the angle between  $\mathbf{A}$  and  $\mathbf{B}$

Ulaby Figure 3-5

**UMBC**  
AN HONORS  
UNIVERSITY  
IN MARYLAND

When  $\theta_{AB} < 90^\circ$ ,  $\mathbf{A} \cdot \mathbf{B} > 0$

When  $\theta_{AB} > 90^\circ$ ,  $\mathbf{A} \cdot \mathbf{B} < 0$

When  $\theta_{AB} = 90^\circ$ ,  $\mathbf{A} \cdot \mathbf{B} = 0$ , and the vectors are called *orthogonal*

6.5

There are three types of multiplication that we must consider: (1) A scalar (single number) x a vector  $\rightarrow$  a vector, (2) (a vector) x (a vector)  $\rightarrow$  scalar [the dot product], and (3) (a vector) x (a vector)  $\rightarrow$  (a vector) [the cross product].

NOTE: Strictly speaking the cross product does not produce a vector; it produces a pseudo-vector. A pseudo-vector is actually an AREA. The length of the vector corresponds to the magnitude of the area and its orientation is at right angles to the plane of the area. The difference between a pseudo-vector and a real vector is not important in this course.

## Vector Algebra

### Multiplication — Scalar or Dot Product

We have

$$\hat{\mathbf{x}} \cdot \hat{\mathbf{x}} = \hat{\mathbf{y}} \cdot \hat{\mathbf{y}} = \hat{\mathbf{z}} \cdot \hat{\mathbf{z}} = 1$$

$$\hat{\mathbf{x}} \cdot \hat{\mathbf{y}} = \hat{\mathbf{y}} \cdot \hat{\mathbf{z}} = \hat{\mathbf{x}} \cdot \hat{\mathbf{z}} = 0$$

so that

$$\begin{aligned}\mathbf{A} \cdot \mathbf{B} &= (\hat{\mathbf{x}}A_x + \hat{\mathbf{y}}A_y + \hat{\mathbf{z}}A_z) \cdot (\hat{\mathbf{x}}B_x + \hat{\mathbf{y}}B_y + \hat{\mathbf{z}}B_z) \\ &= A_xB_x + A_yB_y + A_zB_z\end{aligned}$$

Other properties:

$$\mathbf{A} \cdot \mathbf{B} = \mathbf{B} \cdot \mathbf{A} \quad (\text{commutative})$$

$$\mathbf{A} \cdot (\mathbf{B} + \mathbf{C}) = \mathbf{A} \cdot \mathbf{B} + \mathbf{A} \cdot \mathbf{C} \quad (\text{distributive})$$

Ulaby Figure 3-5

## Vector Algebra

### Multiplication — Vector or Cross Product

The vector or cross product of two vectors

**A** and **B** is defined by

$$\mathbf{A} \times \mathbf{B} = \hat{\mathbf{n}} AB \sin \theta_{AB}$$

where  $\theta_{AB}$  is the angle *from A to B*  
and  $\hat{\mathbf{n}}$  is a unit vector determined by  
the right-hand rule

(a) Cross product

(b) Right-hand rule

Ulaby Figure 3-6

The vector product is *anti-commutative*

$$\mathbf{A} \times \mathbf{B} = -\mathbf{B} \times \mathbf{A}$$

and distributive

$$\mathbf{A} \times (\mathbf{B} + \mathbf{C}) = \mathbf{A} \times \mathbf{B} + \mathbf{A} \times \mathbf{C}$$

**UMBC**  
AN HONORS  
UNIVERSITY  
IN MARYLAND

$$\hat{\mathbf{x}} \times \hat{\mathbf{x}} = \hat{\mathbf{y}} \times \hat{\mathbf{y}} = \hat{\mathbf{z}} \times \hat{\mathbf{z}} = 0$$

$$\hat{\mathbf{x}} \times \hat{\mathbf{y}} = \hat{\mathbf{z}}, \quad \hat{\mathbf{y}} \times \hat{\mathbf{z}} = \hat{\mathbf{x}}, \quad \hat{\mathbf{z}} \times \hat{\mathbf{x}} = \hat{\mathbf{y}}$$

The direction in which  $\theta_{AB}$  is determined matters in this case.

## Vector Algebra

### Multiplication — Vector or Cross Product

We have

$$\hat{\mathbf{x}} \times \hat{\mathbf{x}} = \hat{\mathbf{y}} \times \hat{\mathbf{y}} = \hat{\mathbf{z}} \times \hat{\mathbf{z}} = 0$$

$$\hat{\mathbf{x}} \times \hat{\mathbf{y}} = \hat{\mathbf{z}}, \quad \hat{\mathbf{y}} \times \hat{\mathbf{z}} = \hat{\mathbf{x}}, \quad \hat{\mathbf{z}} \times \hat{\mathbf{x}} = \hat{\mathbf{y}}$$

so that

$$\begin{aligned} \mathbf{A} \times \mathbf{B} &= (\hat{\mathbf{x}}A_x + \hat{\mathbf{y}}A_y + \hat{\mathbf{z}}A_z) \times (\hat{\mathbf{x}}B_x + \hat{\mathbf{y}}B_y + \hat{\mathbf{z}}B_z) \\ &= \hat{\mathbf{x}}(A_yB_z - A_zB_y) + \hat{\mathbf{y}}(A_zB_x - A_xB_z) \\ &\quad + \hat{\mathbf{z}}(A_xB_y - A_yB_x) \end{aligned}$$

We may also write

$$\mathbf{A} \times \mathbf{B} = \begin{vmatrix} \hat{\mathbf{x}} & \hat{\mathbf{y}} & \hat{\mathbf{z}} \\ A_x & A_y & A_z \\ B_x & B_y & B_z \end{vmatrix}$$

**UMBC**  
AN HONORS  
UNIVERSITY  
IN MARYLAND

*This determinant form is very useful!*

Ulaby Figure 3-6

## Vector Algebra

### Summary of vector products

Product type	Product elements	Representation
Simple product	(Scalar) $\times$ (Vector) $\rightarrow$ Vector	$\mathbf{C} = k\mathbf{A}$
Scalar product or Dot product	(Vector) $\times$ (Vector) $\rightarrow$ Scalar	$\mathbf{C} = \mathbf{A} \cdot \mathbf{B}$
Vector product or Cross product	(Vector) $\times$ (Vector) $\rightarrow$ Vector	$\mathbf{C} = \mathbf{A} \times \mathbf{B}$

Strictly speaker, the (vector) $\times$ (vector) product produces a PSEUDO-VECTOR or a 2-form. It can be thought of as an area. The magnitude of the area is given by the length of the pseudo-vector, and the direction of the pseudo-vector is orthogonal to the plane of the area.

## Vector Algebra

### Vectors and Angles: Ulaby et al. Example 3-1

**Question:** In Cartesian coordinates, vector **A** is directed from the origin to the point  $P_1(2, 3, 3)$ , and vector **B** is directed from  $P_1$  to  $P_2(1, -2, 2)$ . Find (a) the vector **A**, its magnitude  $A$ , and its unit vector  $\hat{\mathbf{a}}$ , (b) the angle that **A** makes with the  $y$ -axis, (c) vector **B**, (d) the angle between **A** and **B**, and (e) the perpendicular distance from the origin to **B**.

**Answer:** (a)

$$\mathbf{A} = \hat{\mathbf{x}} 2 + \hat{\mathbf{y}} 3 + \hat{\mathbf{z}} 3$$

$$A = \sqrt{4 + 9 + 9} = \sqrt{22}$$

$$\hat{\mathbf{a}} = \mathbf{A} / A = (\hat{\mathbf{x}} 2 + \hat{\mathbf{y}} 3 + \hat{\mathbf{z}} 3) / \sqrt{22}$$

UNIVERSITY  
IN MARYLAND

6.10

## Vector Algebra

Vectors and Angles: Ulaby et al. Example 3-1

**Answer (continued):** (b) The angle  $\beta$  between  $\mathbf{A}$  and the  $y$ -axis may be found from the expression  $\mathbf{A} \cdot \hat{\mathbf{y}} = A \cos \beta$ , which implies

$$\beta = \cos^{-1} \left( \frac{\mathbf{A} \cdot \hat{\mathbf{y}}}{A} \right) = \cos^{-1} \left( \frac{3}{\sqrt{22}} \right) = 0.879 \text{ rads} = 50.2^\circ$$

(c)  $\mathbf{B} = \hat{\mathbf{x}}(1-2) + \hat{\mathbf{y}}(-2-3) + \hat{\mathbf{z}}(2-3) = -\hat{\mathbf{x}} - \hat{\mathbf{y}}5 - \hat{\mathbf{z}}$

(d)  $\theta = \cos^{-1} \left( \frac{\mathbf{A} \cdot \mathbf{B}}{AB} \right) = \cos^{-1} \left( \frac{-20}{\sqrt{22}\sqrt{27}} \right)$   
 $= 2.533 \text{ rads} = 145.1^\circ$

(e) The points  $OP_1P_3$  form a right triangle.

The magnitude of the line segment  $OP_3$  is given by

$$A \sin(\pi - \theta) = \sqrt{22} \sin(0.609) = 2.68$$

Ulaby Figure 3-7

6.11

## Vector Algebra

---

### Triple Scalar Product

This product can be written in the equivalent forms

$$\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C}) = \mathbf{B} \cdot (\mathbf{C} \times \mathbf{A}) = \mathbf{C} \cdot (\mathbf{A} \times \mathbf{B})$$

The equivalence can be demonstrated from the determinant representation

$$\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C}) = \begin{vmatrix} A_x & A_y & A_z \\ B_x & B_y & B_z \\ C_x & C_y & C_z \end{vmatrix}$$

The absolute value of this scalar product is the volume of the parallelepiped whose sides are the vectors  $\mathbf{A}$ ,  $\mathbf{B}$ , and  $\mathbf{C}$ .

Note that it is important to keep the right cyclic order. Otherwise, the sign changes.

## Vector Algebra

### Triple Scalar Product

This product can be written in the equivalent forms

$$\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C}) = \mathbf{B} \cdot (\mathbf{C} \times \mathbf{A}) = \mathbf{C} \cdot (\mathbf{A} \times \mathbf{B})$$

It corresponds to the volume of a parallelepiped

**UMBC**  
AN HONORS  
UNIVERSITY  
IN MARYLAND

$$\text{Surface area} = |\mathbf{A} \times \mathbf{B}| = |\mathbf{A}| |\mathbf{B}| \sin \theta$$

$$\text{Volume} = |\mathbf{C} \cdot (\mathbf{A} \times \mathbf{B})| = |\mathbf{A}| |\mathbf{B}| |\mathbf{C}| \sin \theta \cos \phi' = |\mathbf{A}| |\mathbf{B}| |\mathbf{C}| \sin \theta \sin \phi$$

6.13

The triple scalar product can be interpreted “physically” as the volume of a parallelepiped.

## Vector Algebra

---

### Triple Vector Product

This product is defined as

$$\mathbf{A} \times (\mathbf{B} \times \mathbf{C}) \quad \text{and we note} \quad \mathbf{A} \times (\mathbf{B} \times \mathbf{C}) \neq (\mathbf{A} \times \mathbf{B}) \times \mathbf{C}$$

This relationship can also be written in the form

$$\mathbf{A} \times (\mathbf{B} \times \mathbf{C}) = \mathbf{B}(\mathbf{A} \cdot \mathbf{C}) - \mathbf{C}(\mathbf{A} \cdot \mathbf{B})$$

The first note implies that this relationship is not associative.

## Orthogonal Coordinate Systems

---

### Three coordinate systems

Coordinate systems (with three coordinates) specify points in space

Orthogonal systems have coordinates that are mutually perpendicular

— at least locally

There are three coordinate systems that are often used

- Cartesian coordinates  $(x, y, z)$ : Simplest and orthogonal everywhere
- Cylindrical coordinates  $(r, \theta, z)$ 
  - used with optical fibers, coaxial cables, cylindrical waveguides
- Spherical coordinates  $(R, \theta, \phi)$ 
  - used with antenna radiation, radar, earth-ionosphere waveguide

## Three Coordinate Systems

### Summary of vector and differential relations

	Cartesian Coordinates	Cylindrical Coordinates	Spherical Coordinates
Coordinate variables	$x, y, z$	$r, \theta, z$	$R, \theta, \phi$
Vector, $\mathbf{A} =$	$\hat{\mathbf{x}}A_x + \hat{\mathbf{y}}A_y + \hat{\mathbf{z}}A_z$	$\hat{\mathbf{r}}A_r + \hat{\boldsymbol{\phi}}A_\phi + \hat{\mathbf{z}}A_z$	$\hat{\mathbf{R}}A_R + \hat{\boldsymbol{\theta}}A_\theta + \hat{\boldsymbol{\phi}}A_\phi$
Magnitude, $ \mathbf{A}  =$	$(A_x^2 + A_y^2 + A_z^2)^{1/2}$	$(A_r^2 + A_\phi^2 + A_z^2)^{1/2}$	$(A_R^2 + A_\theta^2 + A_\phi^2)^{1/2}$
Position vector for $P(x_1, y_1, z_1)$	$\hat{\mathbf{x}}x_1 + \hat{\mathbf{y}}y_1 + \hat{\mathbf{z}}z_1$	$\hat{\mathbf{r}}r_1 + \hat{\mathbf{z}}z_1$ for $P(r_1, \phi_1, z_1)$	$\hat{\mathbf{R}}R_1$ for $P(R_1, \theta_1, \phi_1)$
Dot product, $\mathbf{A} \cdot \mathbf{B}$	$A_xB_x + A_yB_y + A_zB_z$	$A_rB_r + A_\phi B_\phi + A_zB_z$	$A_RB_R + A_\theta B_\theta + A_\phi B_\phi$
Cross product, $\mathbf{A} \times \mathbf{B}$	$\begin{vmatrix} \hat{\mathbf{x}} & \hat{\mathbf{y}} & \hat{\mathbf{z}} \\ A_x & A_y & A_z \\ B_x & B_y & B_z \end{vmatrix}$	$\begin{vmatrix} \hat{\mathbf{r}} & \hat{\boldsymbol{\phi}} & \hat{\mathbf{z}} \\ A_r & A_\phi & A_z \\ B_r & B_\phi & B_z \end{vmatrix}$	$\begin{vmatrix} \hat{\mathbf{R}} & \hat{\boldsymbol{\theta}} & \hat{\boldsymbol{\phi}} \\ A_R & A_\theta & A_\phi \\ B_R & B_\theta & B_\phi \end{vmatrix}$
Differential length, $d\mathbf{l}$	$\hat{\mathbf{x}}dx + \hat{\mathbf{y}}dy + \hat{\mathbf{z}}dz$	$\hat{\mathbf{r}}dr + \hat{\boldsymbol{\phi}}r d\phi + \hat{\mathbf{z}}dz$	$\hat{\mathbf{R}}dR + \hat{\boldsymbol{\theta}}R d\theta + \hat{\boldsymbol{\phi}}R \sin\theta d\phi$
Differential surface areas	$ds_x = \hat{\mathbf{x}} dydz$ $ds_y = \hat{\mathbf{y}} dzdx$ $ds_z = \hat{\mathbf{z}} dxdy$	$ds_r = \hat{\mathbf{r}} r d\phi dz$ $ds_\phi = \hat{\boldsymbol{\phi}} dzdr$ $ds_z = \hat{\mathbf{z}} r dr d\phi$	$ds_R = \hat{\mathbf{R}} R^2 \sin\theta d\theta d\phi$ $ds_\theta = \hat{\boldsymbol{\theta}} R \sin\theta dR d\phi$ $ds_\phi = \hat{\boldsymbol{\phi}} R dR d\theta$
Differential volume	$dv = dx dy dz$	$dv = r dr d\phi dz$	$dv = R^2 \sin\theta dR d\theta d\phi$

## Cartesian Coordinates

### Differential Relations

Length:  $d\mathbf{l} = \hat{\mathbf{x}} dl_x + \hat{\mathbf{y}} dl_y + \hat{\mathbf{z}} dl_z = \hat{\mathbf{x}} dx + \hat{\mathbf{y}} dy + \hat{\mathbf{z}} dz$

Surface area:  $d\mathbf{s}_x = \hat{\mathbf{x}} dl_y dl_z = \hat{\mathbf{x}} dy dz$  (y-z plane)

$d\mathbf{s}_y = \hat{\mathbf{y}} dz dx = \hat{\mathbf{y}} dx dz$  (x-z plane)

$d\mathbf{s}_z = \hat{\mathbf{z}} dx dy$  (x-y plane)

Volume:  $dV = dx dy dz$

For each coordinate system there are three differential lengths that also determine the differential areas and volumes

**UMBC**  
AN HONORS  
UNIVERSITY  
IN MARYLAND

6.17

NOTE: It doesn't matter whether you write the differentials as  $dzdx$  or  $dx dz$ . The usual convention is the way that Ulaby et al. did it --- in the order in which the elements are usually listed. I did it in cyclical order in the table and both ways here.

Cartesian coordinates are the most important because they are globally, not just locally orthogonal AND their differential lengths do not change, depending on position. The orientation of their unit vectors does not change with position. Hence, they are simplest to use. We use other coordinate systems because they conform better to the complexity of real geometries in some cases.

## Cylindrical Coordinates

$r$  = distance from the  $z$ -axis ( $0 < r < \infty$ )

$\phi$  = angle measured on the  
 $x$ - $y$  plane from the  
 $+x$ -axis ( $0 < \phi < 2\pi$ )

**UMBC**  
AN HONORS  
UNIVERSITY  
IN MARYLAND

Ulaby Figure 3-9 6.18

We will shortly give explicit relations between cylindrical and Cartesian coordinates

In polar or cylindrical coordinates, the direction of  $\hat{r}$  and  $\hat{\phi}$  are position dependent, since the direction of the maximum change of  $r$  and  $\phi$  are position-dependent

By contrast, there is no change in the direction of maximum change of  $x$  and  $y$ , and so  $\hat{x}$  and  $\hat{y}$  always point in the same direction. The direction in which  $r$  changes maximally is also the direction in which  $\phi$  and  $z$  do not change because we have an ORTHOGONAL coordinate system.

In polar or cylindrical coordinates, the direction of  $\hat{r}$  and  $\hat{\phi}$  are position dependent, since the direction of the maximum change of  $r$  and  $\phi$  are position-dependent

By contrast, there is no change in the direction of maximum change of  $x$  and  $y$ , and so  $\hat{x}$  and  $\hat{y}$  always point in the same direction. The direction in which  $r$  changes maximally is also the direction in which  $\phi$  and  $z$  do not change because we have an ORTHOGONAL coordinate system.

Ulaby et al. 2010 Module 3.1. Show that both  $\hat{r}$  and  $\hat{\phi}$  depend on  $\phi$ .

## Cylindrical Coordinates

---

Base vectors

$$\hat{\mathbf{r}} \times \hat{\boldsymbol{\phi}} = \hat{\mathbf{z}}, \quad \hat{\boldsymbol{\phi}} \times \hat{\mathbf{z}} = \hat{\mathbf{r}}, \quad \hat{\mathbf{z}} \times \hat{\mathbf{r}} = \hat{\boldsymbol{\phi}}$$

$$\hat{\mathbf{r}} \cdot \hat{\mathbf{r}} = \hat{\boldsymbol{\phi}} \cdot \hat{\boldsymbol{\phi}} = \hat{\mathbf{z}} \cdot \hat{\mathbf{z}} = 1, \quad \hat{\mathbf{r}} \times \hat{\mathbf{r}} = \hat{\boldsymbol{\phi}} \times \hat{\boldsymbol{\phi}} = \hat{\mathbf{z}} \times \hat{\mathbf{z}} = 0$$

$$\hat{\mathbf{r}} \cdot \hat{\boldsymbol{\phi}} = \hat{\mathbf{r}} \cdot \hat{\mathbf{z}} = \hat{\boldsymbol{\phi}} \cdot \hat{\mathbf{z}} = 0$$

Vector relations

$$\mathbf{A} = \hat{\mathbf{r}} A_r + \hat{\boldsymbol{\phi}} A_\phi + \hat{\mathbf{z}} A_z$$

$$A = |\mathbf{A}| = \sqrt{\mathbf{A} \cdot \mathbf{A}} = \left( A_r^2 + A_\phi^2 + A_z^2 \right)^{1/2}$$

Letting  $P = P(r_1, \phi_1, z_1)$ , the position vector  $\mathbf{R}_1 = OP = \hat{\mathbf{r}} r_1 + \hat{\mathbf{z}} z_1$

We note that the direction of  $\hat{\mathbf{r}}$  depends on  $\phi$

The dependence of the unit vectors on the local coordinates is a property of all orthogonal coordinate systems, EXCEPT CARTESIAN

## Cylindrical Coordinates

### Differential relations

Length:  $d\mathbf{l} = \hat{\mathbf{r}} dl_r + \hat{\boldsymbol{\phi}} dl_\phi + \hat{\mathbf{z}} dl_z = \hat{\mathbf{r}} dr + \hat{\boldsymbol{\phi}} r d\phi + \hat{\mathbf{z}} dz$

Surface area:  $d\mathbf{s}_r = \hat{\mathbf{r}} r d\phi dz$  ( $\phi$ - $z$  plane)

$d\mathbf{s}_\phi = \hat{\boldsymbol{\phi}} dr dz$  ( $r$ - $z$  plane)

$d\mathbf{s}_z = \hat{\mathbf{z}} r dr d\phi$  ( $r$ - $\phi$  plane)

Volume:  $dV = r dr d\phi dz$

Ulaby Figure 3-10

## Spherical Coordinates

$R$  = distance from the origin ( $0 < R < \infty$ )

$\theta$  = angle measured from the  $+z$ -axis ( $0 < \theta < \pi$ ) = *zenith angle*

$\phi$  = angle measured from the  $+x$ -axis on the  $x$ - $y$  plane ( $0 < \phi < 2\pi$ )  
= *azimuthal angle*

Ulaby Figure 3-13 6.23

UMBC  
AN HONORS  
UNIVERSITY  
IN MARYLAND

In an analogy to the globe, theta corresponds to latitude and is measured from the north pole, not the equator; phi corresponds to longitude and is measured from an “arbitrarily chosen” x-axis. (Sometimes we use this geometry where the symmetry is broken, and the choice is no longer arbitrary.) On our globe, we measure longitude from the Greenwich Observatory. While not arbitrary, this choice was long disputed. Historically, the French measured longitude for a long time from the Paris Observatory! This issue was not settled until the late 19-th century.

## Spherical Coordinates

---

Base vectors

$$\hat{\mathbf{R}} \times \hat{\boldsymbol{\theta}} = \hat{\boldsymbol{\phi}}, \quad \hat{\boldsymbol{\theta}} \times \hat{\boldsymbol{\phi}} = \hat{\mathbf{R}}, \quad \hat{\boldsymbol{\phi}} \times \hat{\mathbf{R}} = \hat{\boldsymbol{\theta}}$$

$$\hat{\mathbf{R}} \cdot \hat{\mathbf{R}} = \hat{\boldsymbol{\theta}} \cdot \hat{\boldsymbol{\theta}} = \hat{\boldsymbol{\phi}} \cdot \hat{\boldsymbol{\phi}} = 1, \quad \hat{\mathbf{R}} \times \hat{\mathbf{R}} = \hat{\boldsymbol{\phi}} \times \hat{\boldsymbol{\phi}} = \hat{\boldsymbol{\theta}} \times \hat{\boldsymbol{\theta}} = 0$$

$$\hat{\mathbf{R}} \cdot \hat{\boldsymbol{\theta}} = \hat{\mathbf{R}} \cdot \hat{\boldsymbol{\phi}} = \hat{\boldsymbol{\theta}} \cdot \hat{\boldsymbol{\phi}} = 0$$

Vector relations

$$\mathbf{A} = \hat{\mathbf{a}} A = \hat{\mathbf{R}} A_R + \hat{\boldsymbol{\theta}} A_\theta + \hat{\boldsymbol{\phi}} A_\phi$$

$$A = |\mathbf{A}| = \sqrt{\mathbf{A} \cdot \mathbf{A}} = \left( A_R^2 + A_\theta^2 + A_\phi^2 \right)^{1/2}$$

Letting  $P = P(R_1, \theta_1, \phi_1)$ , the position vector  $\mathbf{R}_1 = OP = \hat{\mathbf{R}} R_1$

In this case, all three directions of the base vectors depend on the position.

## Spherical Coordinates

Differential relations

$$\text{Length: } d\mathbf{l} = \hat{\mathbf{R}} dl_R + \hat{\boldsymbol{\theta}} dl_\theta + \hat{\boldsymbol{\phi}} dl_\phi = \hat{\mathbf{R}} dR + \hat{\boldsymbol{\theta}} R d\theta + \hat{\boldsymbol{\phi}} R \sin \theta d\phi$$

$$\text{Surface area: } d\mathbf{s}_R = \hat{\mathbf{R}} R^2 \sin \theta d\theta d\phi \quad (\theta\text{-}\phi \text{ plane})$$

$$d\mathbf{s}_\theta = \hat{\boldsymbol{\theta}} R \sin \theta dR d\phi \quad (R\text{-}\phi \text{ plane})$$

$$d\mathbf{s}_\phi = \hat{\boldsymbol{\phi}} R dR d\theta \quad (R\text{-}\theta \text{ plane})$$

$$\text{Volume: } dv = R^2 \sin \theta dR d\theta d\phi$$

Ulaby Figure 3-14

The dependence of the unit vectors on the local coordinates is a property of all orthogonal coordinate systems, EXCEPT CARTESIAN

## Spherical Coordinates

Charge in a Sphere: Ulaby et al. Example 3-6

**Question:** A sphere of radius 2 cm contains a charge of density  $\rho_V$  given by  
 $\rho_V = 4 \cos^2 \theta$

What is the total charge?

**Answer:** After converting from cm to m,

$$\begin{aligned} Q &= \int_V \rho_V dv \\ &= \int_{\phi=0}^{2\pi} \int_{\theta=0}^{\pi} \int_{R=0}^{2 \times 10^{-2}} (4 \cos^2 \theta) R^2 \sin \theta dR d\theta d\phi \\ &= 4 \int_0^{2\pi} \int_0^{\pi} \left( \frac{R^3}{3} \right) \bigg|_0^{2 \times 10^{-2}} \sin \theta \cos^2 \theta d\theta d\phi \\ &= \frac{64}{9} \times 10^{-6} \int_0^{2\pi} d\phi = \frac{128\pi}{9} \times 10^{-6} = 44.68 \mu\text{C} \end{aligned}$$

6.26

Note that this example only requires “simple” integral calculus. ALL of Ulaby et al.’s examples on coordinates involve “simple” integral calculus. If you are not completely comfortable with this, you should review it!

## Tech Brief 5: GPS

- Originally developed by DOD
- Originally 24 satellites, now 31
- Operation principles
  - Satellites constantly broadcast a message containing
    - Their location
    - Message time
    - System health and rough orbit details
  - GPS receivers use triangulation to determine location relative to satellites
    - Determine distances to each satellite by solving an equation including the sat. position and time, multiplying by the speed of light.

$$\begin{aligned}d_1^2 &= (x_1 - x_0)^2 + (y_1 - y_0)^2 + (z_1 - z_0)^2 = c [(t_1 + t_0)]^2, \\d_2^2 &= (x_2 - x_0)^2 + (y_2 - y_0)^2 + (z_2 - z_0)^2 = c [(t_2 + t_0)]^2, \\d_3^2 &= (x_3 - x_0)^2 + (y_3 - y_0)^2 + (z_3 - z_0)^2 = c [(t_3 + t_0)]^2, \\d_4^2 &= (x_4 - x_0)^2 + (y_4 - y_0)^2 + (z_4 - z_0)^2 = c [(t_4 + t_0)]^2.\end{aligned}$$

Four satellites are needed to correct for the imprecise receiver clock (quartz).

6.27

## Tech Brief 5: Differential GPS

- GPS accuracy: 20-30m
- Differential GPS (DGPS) uses a static reference of known location in the receiver's area to correct for inaccuracy factors
  - Time-delay errors (speed of light differences)
  - Multipath interference
  - Satellite location errors
- Reference receiver calculates correction factors and transmits to DGPS receivers in the area
