

# iOS Security

9 May 2018

# But First

- ♦ <https://ai.googleblog.com/2018/05/duplex-ai-system-for-natural-conversation.html>
- ♦ <https://www.theverge.com/2018/5/8/17332480/google-maps-augmented-reality-directions-walking-ar-street-view-personalized-recommendations-voting>

# Apple Devices

iOS, not Mac OS

# Source

- ♦ [https://www.apple.com/business/docs/iOS\\_Security\\_Guide.pdf](https://www.apple.com/business/docs/iOS_Security_Guide.pdf)
- ♦ This tells many of the high level concepts, but does not get into the bits and blips of security at Apple.

# Introduction of the iPhone

- ♦ Introduction: 29 June 2007
- ♦ The Steve Jobs reality distortion field.
- ♦ Steve Jobs introduces the iPhone: 3 minutes
- ♦ <https://www.youtube.com/watch?v=MnrJzXM7a6o>

# Apple vs Android

- ♦ All software running on Apple iOS is blessed and approved by Apple.
- ♦ You can get an iPhone directly from Apple without all the adware of Droid. This happened early when AT&T wanted to get into the market badly.
- ♦ Enables software fixes to be implemented quickly when a problem is found.
- ♦ Droid requires Google to make an update. Then the Verizon/ AT&T have to update their adware.
- ♦ Droids are more flexible. You can modify them if you wish.

# Hints

- ♦ I will cover a lot of steps in making an iOS device secure.
- ♦ At the end of each concept, I will tell you what I want you to remember.

# iOS System Security

- ♦ iOS System Security
  - ♦ Secure Boot Chain
  - ♦ System software authorization
  - ♦ Secure Enclave
  - ♦ Touch ID

# Secure Boot Chain

- ◆ Ensure system security is designed so that both hardware and software are secure across all core components of every iOS device.
- ◆ You cannot run any software on iOS without approval from Apple.
- ◆ Other than money, what technical reason is there that iOS will not run on a non Apple device?

# Secure Boot Chain

- ♦ Each step of startup process has components, h/w and s/w that are crypto signed.
- ♦ This ensures integrity and authentication
- ♦ CIAN
- ♦ When iOS device is booted, the application runs code from read only memory called the Boot ROM.
- ♦ Contains the Apple root CA **public** key

# Secure Boot Chain

- ♦ Verifies the Low-Level Bootloader (LLB) is signed by Apple before allowing it to load.
- ♦ LLB runs the next-stage boot loader, iBoot which in turn verifies and runs the iOS Kernel. This means the ROM is signed by Apple.
- ♦ This ensures from the time the device is booted, only Apple approved hardware and software are running.
- ♦ Else, we will not go any further.

# Secure Boot Chain

- ♦ Latest CPU from Apple is A11. Designed by Apple.
  - ♦ iPad
  - ♦ iPhone 8 and 10
- ♦ Includes Secure Enclave Coprocessor (will discuss this coming up). This also uses the secure boot to ensure the hardware and software are verified and signed.
- ♦ If any of these processes fail, device will go in recovery mode. This is called fail, closed. This is a good thing.

# System Software Authorization

- ♦ How do updates get to Apple devices?
- ♦ Apple provides regular updates to iOS for all supported devices.
- ♦ Only Apple signed code from the App Store will be pushed.
- ♦ Each update is uniquely customized to the software on each device.
- ♦ Since every Apple device contains only software approved by Apple, updates can be quick if a problem is found.
- ♦ Apple has a forced update. Only used twice.
- ♦ This is different on Android and since the phone has value added software from a carrier. (Except Google Pixel)

# System Software Authorization

- ♦ During an iOS upgrade, iTunes connects to the Apple installation authorization server. This happens even when locked. It must be on WiFi.
- ♦ Sends a list of cryptographic keys for the software to be run on this device
- ♦ Also, sends a nonce and the device's Unique ID. (ECID)
- ♦ The UID is not stored at Apple. This is only on the device and is unique to each iPhone.
- ♦ Authorization server checks the registered device and what it is allowed to have. For example, an iPhone 4S lacks iPay, the fingerprint reader features on a iPhone 6. And the iPhone X has FaceID.

# System Software Authorization

- ♦ Boot time chain of trust evaluation on the device verifies the signature came from Apple.
- ♦ Going to a previous level of software is not allowed. Why?
- ♦ A nonce is used to further assist in crypto and prevent a replay attack.

# System Software Authorization

- ♦ A lot of slides were presented.
- ♦ Summary:
  - ♦ The h/w and s/w is signed
  - ♦ Crypto is used to ensure only Apple approved s/w and h/w is on this device.
  - ♦ Each device receives a customized update.

# Secure Enclave

- ♦ The Secure Enclave is a physical coprocessor in the Apple CPU
- ♦ Stores the passcode and representation of fingerprint
  - ♦ In other words, it is the `/etc/password` and `/etc/shadow`
- ♦ This is for authentication, but not authorization
- ♦ Provides all crypto operations for Data Protection key management
- ♦ Maintains the integrity even if the kernel has been compromised.
- ♦ It utilizes its own secure boot.

# Secure Enclave

- ◆ Uses encrypted memory
- ◆ A UID is the equivalent to a serial number burned into each processor that identifies each processor's Secure Enclave uniquely.
- ◆ Apple claims the UID is not directly accessible by other parts of the device.
- ◆ This information is stored in regular memory, but encrypted using the key, UID.
- ◆ When a UID or any other information is stored on a chip, it is very difficult to directly access.

# Secure Enclave

- ♦ Responsible for determining the validity of a fingerprint, or a face.
- ♦ Processor sends the “measurement” of the fingerprint or face to the Secure Enclave, but cannot read it.
- ♦ The Secure Enclave responds with a yes or no answer. Is there a match?
- ♦ Even though the CPU and Secure Enclave are in the same device, they are physically separate.

# Secure Enclave

- ♦ The measurement of the finger print is encrypted and authenticated with a session key in the Secure Enclave.
- ♦ Session key exchange uses AES key wrapping with both sides providing a random key.
- ♦ This is seriously complicated encryption by Apple.

# Secure Enclave

## Just the facts

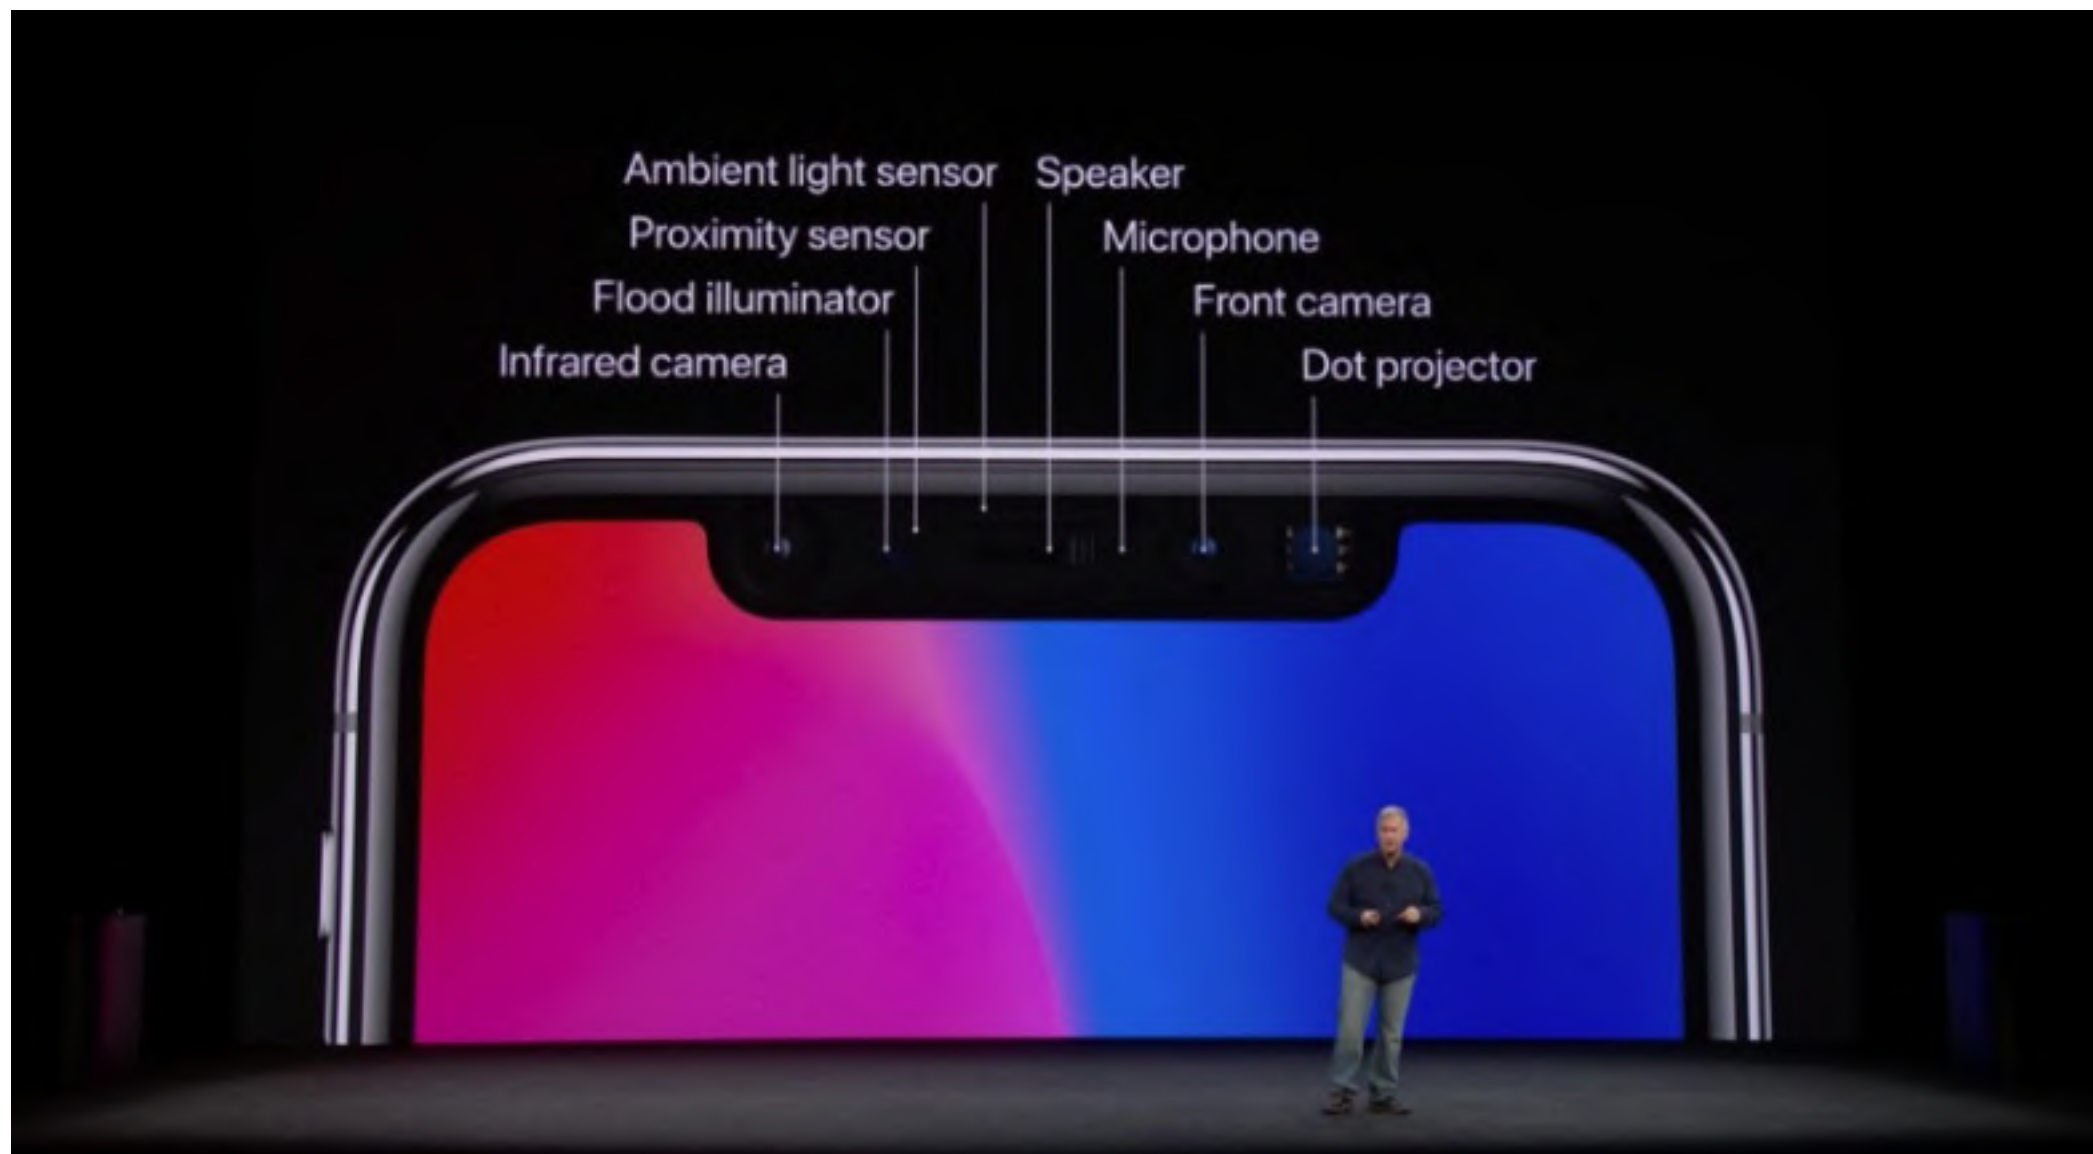

- ♦ The Secure Enclave holds the fingerprint and pass code.
- ♦ The Secure Enclave is separate from the CPU.
- ♦ The CPU verifies the authenticity of the user.

# Finger Print Reader

## Touch ID

# iPhone 10 Sensors

# Touch ID

- ◆ Fingerprint reader
- ◆ Goal is to replace passwords
- ◆ Fingerprints are unique
- ◆ Makes a longer more complex password
- ◆ Allows you to log in to some enabled applications

# Touch ID

- ♦ Passcode can always be used instead of TouchID
- ♦ Required in the following cases:
  - ♦ Device has been restarted
  - ♦ Has not been unlocked for > 48 hours
  - ♦ Has received a remove lock command
  - ♦ Five unsuccessful attempts to match fingerprint
  - ♦ Enrolling new finger in TouchID

# Touch ID

## Just the facts

- ♦ Used most of the time instead of pass code.
- ♦ Pass code can be used at all times.
- ♦ Touch ID cannot be used at all times.

# Encryption and Data Protection

- ◆ Coming up:
  - ◆ **Hardware Security Features**
  - ◆ File Data Protection
  - ◆ Passcodes
  - ◆ *Data Protections classes*
  - ◆ *Keychain Data Protection*

# Hardware Security Features

- ♦ A11 is an ARM processor. This is a RISC chip.
  - ♦ **A**corn **RISC Machine** or **A**dvanced **RISC Machine**
- ♦ Mobile devices run on a battery.
- ♦ Crypto operations are complex
- ♦ Each iOS devices has a dedicated AES crypto engine.
- ♦ This engine is built into the DMA path between flash and system memory.
- ♦ For performance and energy savings.

# Hardware Security Features

- ♦ Secure Enclave has in hardware:
  - ♦ Device Unique ID (UID)
  - ♦ Device group id (GID) Identifies hardware
- ♦ UID is unique for each device. Apple claims it cannot read it.
- ♦ This ensures that the software installed on one computer cannot be run on another.
- ♦ Discourages forensics
- ♦ Software is tied to a single device.
  - ♦ Cannot install a license and run it on another computer

# Hardware Security Features

- ♦ Wear leveling means multiple copies of keys might exist.
- ♦ Spinning drives have bad sections.
- ♦ Forensics tools might be able to find.
- ♦ Effaceable Storage resolves this with secure erase.

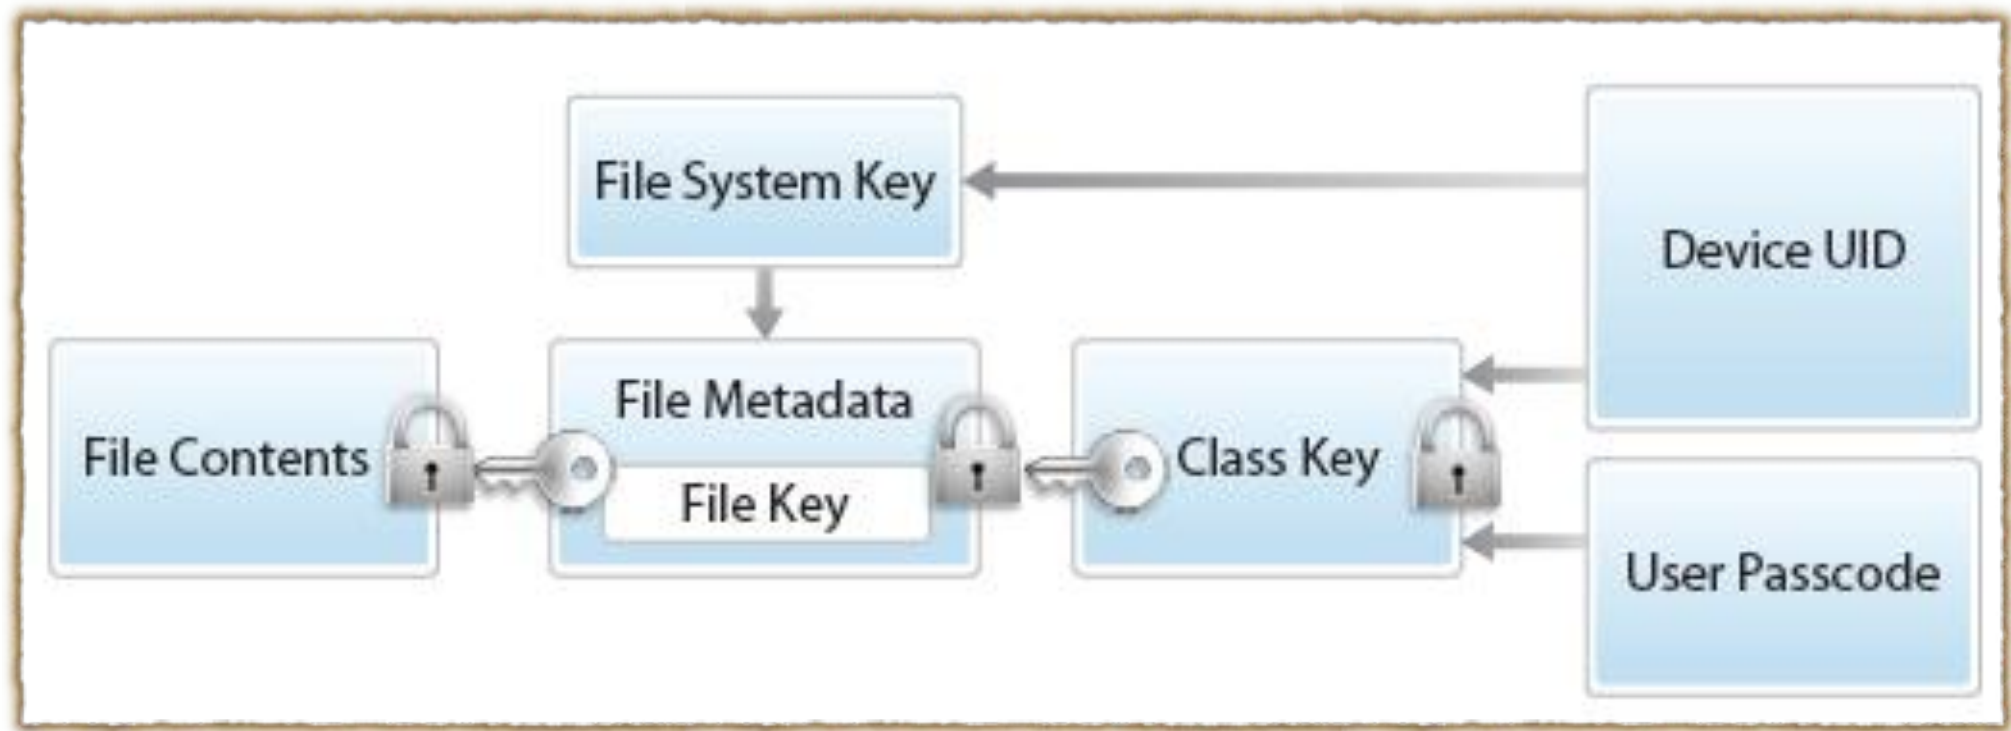

# Encryption and Data Protection

- ◆ Coming up:
  - ◆ Hardware Security Features
  - ◆ **File Data Protection**
  - ◆ Passcodes
  - ◆ *Data Protections classes*
  - ◆ *Keychain Data Protection*

# File Data Protection

- ♦ When a file is created, Data Protection creates a new 256 bit key
- ♦ Key given to AES encryption engine to encrypt the file.
- ♦ Also, the meta data is encrypted

# Keys involved in opening a file

# Erase the Device

- ♦ To zero out the device memory, what needs to be done?

# Erase the Device

- ♦ To initialize the device, what needs to be done?
- ♦ Clear Effaceable Storage
- ♦ Actually, any of the above key should do it.
- ♦ Even if you have forensics tools, you still have to decrypt the data once you got it off the device.

# Encryption and Data Protection

- ◆ Coming up:
  - ◆ Hardware Security Features
  - ◆ File Data Protection
  - ◆ **Passcodes**
  - ◆ *Data Protections classes*
  - ◆ *Keychain Data Protection*

# Passcodes

- ♦ Setting up a passcode enables Data Protection.
- ♦ Provides entropy for certain encryption keys
- ♦ Touch ID allows you to have a longer passcode.
- ♦ The longer the passcode, the more secure the device.

# New in iOS 11.4

- ♦ <https://blog.malwarebytes.com/security-world/2018/03/graykey-iphone-unlocker-poses-serious-security-concerns/>
- ♦ Lightning port will be disabled to data after 7 days of not accessing the device.
- ♦ Power still works.
- ♦ Either by passcode, fingerprint, or facial recognition.

# Summary

- ◆ Secure Boot Chain
- ◆ System software authorization
- ◆ Secure enclave structure
- ◆ Files are encrypted to include meta data

# Last slide

- ◆ See subject.
